

## 5.1 Induction, continued

p.1

As we saw last time, mathematical induction can be used to prove a series of propositions  $P(n)$  for  $n=1, 2, 3, \dots$ . Use 4 steps:

- (A) Identify what  $P(n)$  says.
- (B) Check the basis step  $P(1)$ .
- (C) Verify the inductive step by showing that if  $P(k)$  is true (for any  $k$ ) then  $P(k+1)$  must be true. It can be a good idea to write out what  $P(k)$  and  $P(k+1)$  say and compare.
- (D) "So by mathematical induction  $P(n)$  is true for all  $n \geq 1$ ."

More examples.

① Prove that  $1 + 3 + 3^2 + \dots + 3^n = \frac{3^{n+1} - 1}{2}$  for all  $n \geq 1$ .

Solution: (A)  $P(n)$  says  $1 + 3 + 3^2 + \dots + 3^n = \frac{3^{n+1} - 1}{2}$

(B)  $P(1)$  says  $1 + 3^1 = \frac{3^{1+1} - 1}{2}$

$$4 = \frac{9 - 1}{2} \quad \text{true } \checkmark$$

this verifies the basis step.

(C) To verify the inductive step, we start by assuming  $P(k)$  is true (replace  $n$  by  $k$  in  $P(n)$ )

$$1 + 3 + 3^2 + \dots + 3^k = \frac{3^{k+1} - 1}{2} \quad \boxed{\text{true}}$$

Use this to prove  $P(k+1)$  is true.  $P(k+1)$  says

$$1+3+3^2+\dots+3^k+3^{k+1} = \frac{3^{k+1}-1}{2} \quad (*)$$

Compare the left sides of  $P(k)$  and  $P(k+1)$ .  
Add  $3^{k+1}$  to both sides of  $P(k)$ :

$$1+3+3^2+\dots+3^k+3^{k+1} = \frac{3^{k+1}-1}{2} + 3^{k+1} \quad \boxed{\text{true}}$$

$$\frac{3^{k+1}-1}{2} + \frac{2 \cdot 3^{k+1}}{2} \quad \leftarrow \text{simplify}$$

$$= \frac{3^{k+1} + 2 \cdot 3^{k+1} - 1}{2}$$

$$= \frac{(1+2)3^{k+1} - 1}{2} = \frac{3 \cdot 3^{k+1} - 1}{2}$$

$$= \frac{3^{k+2} - 1}{2}$$

So  $P(k)$  implies that

$$1+3+3^2+\dots+3^{k+1} = \frac{3^{k+2}-1}{2}$$

which is  $(*)$  and  $P(k+1)$ . This finishes the inductive step.

① So by mathematical induction  $P(n)$  is true for all  $n \geq 1$ .

---

2.

Example 2 Prove the inequality  $n < 2^n$  is true for all  $n \geq 0$ .

Solution: (A)  $P(n)$  says  $n < 2^n$ . (B) The basis step is for  $n=0$  this time

$P(0)$  says  $0 < 2^0$  true because  $2^0=1$ .

(C) For the inductive step assume  $P(k)$  is true

$$k < 2^k$$

and use this to prove  $P(k+1)$  i.e.  $k+1 < 2^{k+1}$ .

Comparing the right sides its use to see that  $2^{k+1} = 2 \cdot 2^k = 2^k + 2^k$ .

$$P(k): \quad k < 2^k \quad \text{true}$$

$$\text{so } k+1 < 2^k + 1 \quad \text{true}$$

$$\text{so } k+1 < 2^k + 2^k \quad \text{true}$$

$$\text{so } k+1 < 2^{k+1} \quad \text{true} \quad (1 \leq 2^k \text{ for } k \geq 0)$$

and this is  $P(k+1)$ . We've finished the inductive step.

(D) By the principle of induction,  $P(n)$  is true for all  $n \geq 0$ .

---

Example (3) Prove that  $n^3 - n$  is divisible by 3 for  $n \geq 0$ .

To get an understanding of the problem let's look at it for different  $n$ s first

$$n=0 \quad n^3 - n = 0 - 0 = 0 \quad 3|0 \quad \checkmark$$

$$n=1 \quad n^3 - n = 1 - 1 = 0 \quad 3|0 \quad \checkmark$$

$$n=2 \quad n^3 - n = 2^3 - 2 = 6 \quad 3|6 \quad \checkmark$$

$$n=3 \quad n^3 - n = 3^3 - 3 = 24 \quad 3|24 \quad \checkmark$$

$$n=4 \quad n^3 - n = 64 - 4 = 60 \quad 3|60 \quad \checkmark$$

⋮

looks good, but to prove it for all  $n$  we need induction.

Solution:  $P(n)$  says  $3|n^3 - n$ .

Basis step  $P(0)$  is true we saw.

Inductive step - assume  $P(k)$  is true so

$$3 \text{ divides } k^3 - k$$

use this to show that  $P(k+1)$  is true

$$P(k+1) \text{ says } 3|(k+1)^3 - (k+1)$$

We want to simplify  $(k+1)^3 - (k+1)$  and compare it to  $k^3 - k$ :

$$\begin{aligned} (k+1)^3 - (k+1) &= k^3 + 3k^2 + 3k + 1 - k - 1 \\ &= k^3 - k + 3k^2 + 3k \end{aligned}$$

Now we can see that if  $3 \mid k^3 - k$  then we must have

$$3 \mid k^3 - k + 3k^2 + 3k$$

(because if  $k^3 - k = 3m$  then

$$k^3 - k + 3k^2 + 3k = 3(m + k^2 + k))$$

This finishes the inductive step. By induction  $P(n)$  is true for all  $n \geq 0$ .

Example (4) Prove that the number of bit strings of length  $n$  is  $2^n$  for  $n \geq 0$ .

Remember that bit strings look like

1001011010 for example.

This one has length 10.

Solution:  $P(n)$  says the number of bit strings of length  $n$  is  $2^n$ .

**Basis step**  $n=0$ . There is  $1 = 2^0$  bit string of length 0 (the empty string). Since that's a strange case we can check a few more

$n=1$       0, 1       $2^1 = 2$  strings

$n=2$       00, 01, 10, 11       $2^2 = 4$  strings

$n=3$       000, 001, 010, 011, 100, 101, 110, 111

$2^3 = 8$  strings.

**Inductive step**: Assume  $P(k)$  is true, so there are  $2^k$  bit strings of length  $k$ .

How many bit strings of length  $k+1$ ?

So  $2^k \cdot 2 = 2^{k+1}$  possibilities

If  $P(k)$  is true there must be  $2^{k+1}$  bit strings of length  $k+1$ , so  $P(k+1)$  is true. By induction  $P(n)$  true for all  $n \geq 0$ .

We can use this example to show that a set  $X$  with  $n$  elements must have  $2^n$  subsets i.e.  $|P(X)| = 2^n$ . Every bit string of length  $n$  corresponds to a subset  
 for example  $\{a, b, c, d, e, f\}$ ,  $\{a, b, d\}$   
 $n=6$       1 1 1 1 1 1      1 1 0 1 0 0
